# Design approach

- › Step 1: Line up calculation with losses
- › Step 2: Obtain Main section driver power requirement
- › Step 3: Choose the available LDMOS die that delivers the power
- › Step 4: Design/performance criteria
  - › Compression X dB <1,
  - › Px dB > 33 dBm
  - › As high Gt as possible
  - › As high η% as possible
- › Bondwire + Moscap to improve performance
  - › Select Moscap DOE

# From: Dual driver Architecture-Draft (Alireza)

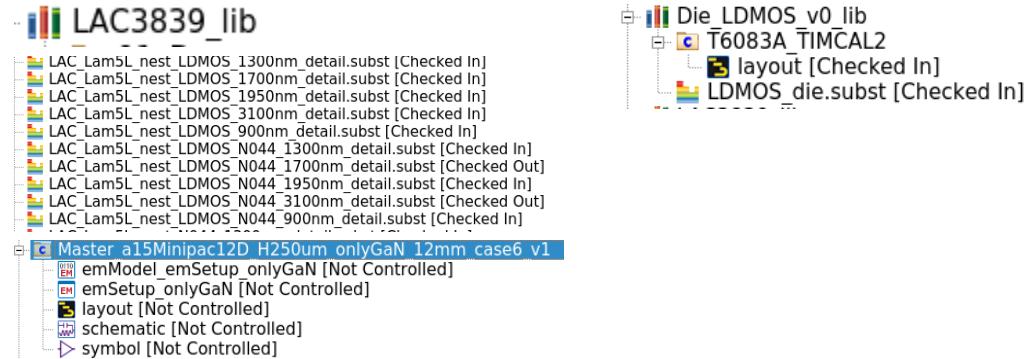

- › Around 33 dBm expected from main section
- › Intended to operate in as much linear region as possible until Pout = 33 dBm

# Design on laminate DOE15

## › Laminate library:LAC3839\_lib

# LDMOS model

## LDMOS models,

- Model validation I was never involved here. I have the model itself, and we could theoretically even support and improve this in the future, but I don't have validation data or report.

You need to go to the 'ELMO2' palette (there are many palettes)

T40xx = LD10

T60xx = LD12 (LD10S)

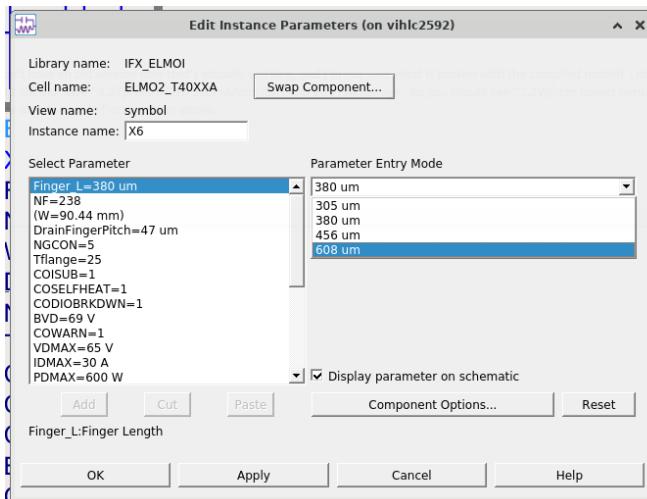

Anything marked with LH1 is 50V LDMOS – poor performance >1GHz.

I believe the LD11 model was discontinued – and in any case for a plastic OM product we shouldn't consider LD11.

[\\mucsdv534.infineon.com\RFS\PG\\_WI\90\\_TechInfo\LDMOS\PDK\\_Model](\\mucsdv534.infineon.com\RFS\PG_WI\90_TechInfo\LDMOS\PDK_Model)

# Design Notes

Right Finger length is not Available, So only 2.28 mm can be made (Interested 2.4mm)

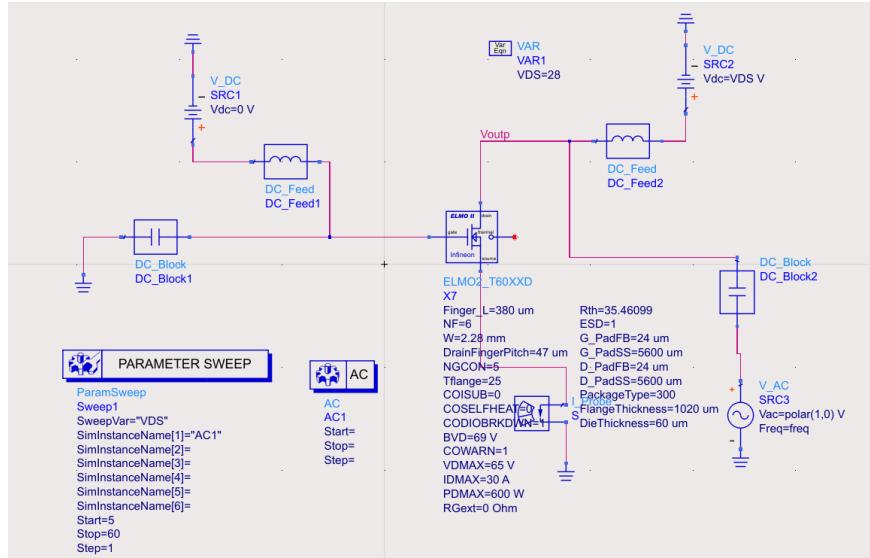

| Fab Name | Marketing Name | Comment   |
|----------|----------------|---|
| LD10M    | LD10           | Oldest run material, Sinker (no TSV) and no voids     |
| LD10E    | LD11           | LD10M with 'open' voids. Not suitable for plastic     |
| LD10S    | LD12           | High res+TSV and integrated capped voids for low Cds. |

So if you are using LD10S, this is not the same thing as LD10.

# CDS checking

N.B. I don't have an old version now that's actually working, and I'm not sure what is broken with the compiled model! Let's looks carefully at the results you get.

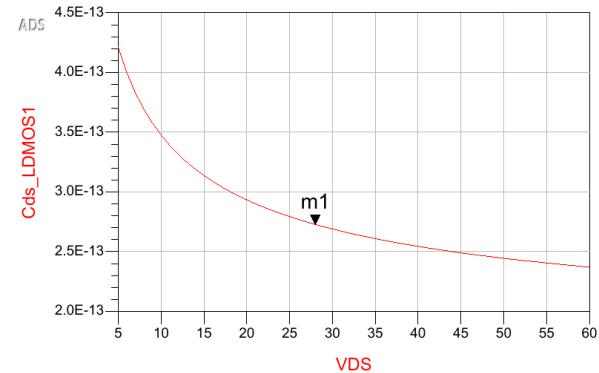

N.B. LD12 should have  $\sim 0.27\text{pF/mm}$  Cds, 110mA/mm ISAT and 28V rail voltage. So you should see  $\sim 1.2\text{W/mm}$  power density and the Cout should let you roughly estimate the load contours. If you get strange results you should be able to realise from number above.

$$\text{Eqn } Z_{out\_p} = V_{outp}/S_i$$

$$\text{Eqn } C_{ds\_LDMOS1} = 1/(2 * 4.56 * \pi * AC.freq * -\text{imag}(Z_{out\_p}))$$

```
m1
indep(m1)=28.000
plot_vs(Cds_LDMOS1,VDS)=2.728E-13
freq=3.600E9
```
